U. S. Army Natick Laboratories, Natick, Mass. DESIGN TABLES FOR COTTON FABRICS: TABLES OF SOLUTIONS OF EQUATIONS FOR COVER FACTOR, BETA FACTOR AND MAXIMUM WEAVABILITY FOR COTTON FABRICS by Louis L. Weiner and Jesse E. Johnston, Jr., August 1964, 157 pp., illus. (Textile Series Report 128).

This report contains in tabular form the solutions of the equations for cover factor, beta factor, and maximum weavability for the entire practical range of cotton yarn counts, textures, and basic weave types--including the plain, oxford, 3- and 4-harness twills, and 5-harness sateen. The tables provide immediate solutions to those design parameters that are routinely used by the fabric designer and the textile engineer working on the geometry of textile structures. Included as appendixes are the text of the original report (by Love) which describes the derivation of the maximum weavability equations from Peirce's relationships, and also the computer program that was used for solving these equations for the practical range of textile variables.

FOREWORD

The U.S. Army Natick Laboratories, as part of its program in textile development, has made a number of studies to characterize the geometry of textile fabrics. The purpose has been to facilitate fabric designing and the interpreting and predicting of the changes that occur in fabric geometry through shrinkage and wear.

Previous Textile Series Reports developed equations, nomographs and graphs to simplify the prediction of construction parameters and of maximum weavability fabrics. The tables in this report provide solutions to the equations previously developed, and thus eliminate the need for practically all intermediate computations, as well as the graphical techniques formerly used for obtaining the solutions to maximum weavability problems.

In making these tables available, we hope to stimulate the wider use of mathematical techniques in simplifying the designing of textile fabrics and to encourage further studies of the relationships between fabric geometry and performance.

Appreciation is expressed to the Computer Branch of the U.S. Army Natick Laboratories for the use of their GE 225 Computer and to Mr. David Gracia and Lt. George H. Haines, Jr., both of the Computer Branch, for writing the program for the solutions to the equations.

We wish to acknowledge especially the important contributions to Army studies of fabric geometry made by Mr. Louis Love of the Defense Supply Agency and Professor Stanley Backer of MIT, both of whom were formerly with the Quartermaster Research and Development Laboratories in Philadelphia, Pa., where much of the work in this field had its inception; to Dr. E. Van Painter of Johnson and Johnson; to Dr. Walter J. Hamburger and Dr. Milton M. Platt of the Fabric Research Laboratories; and to Professor Douglas P. Adams and the late Professor Edward R. Schwarz of MIT.

CONTENTS (Cont'd)

ABSTRACT

This report contains in tabular form the solutions of the equations for cover factor, beta factor, and maximum weavability for the entire practical range of cotton yarn counts, textures, and basic weave types--including the plain, oxford, 3- and 4-harness twills, and 5-harness sateen. The tables provide immediate solutions to those design parameters that are routinely used by the fabric designer and the textile engineer working on the geometry of textile structures. Included as appendixes are the text of the original report (by Love) which describes the derivation of the maximum weavability equations from Peirce's relationships, and also the computer program that was used for solving these equations for the practical range of textile variables.

TABLES OF SOLUTIONS OF EQUATIONS FOR COVER FACTOR, BETA FACTOR AND MAXIMUM WEAVABILITY FOR COTTON FABRICS

1. Purpose and Scope

a.. Purpose

The tables in this report are presented to facilitate the designing of high-texture or maximum-weavability fabrics. Maximum-weavability fabrics are the largest class of functional fabrics used by industry and the military. Among many weaves they include: ducks, poplins, wind-resistant twills and sateens, airplane and balloon cloths, and linings. Most other commercial fabrics are designed to a certain percentage of maximum weavability and it is always of concern to the designer to know whether his fabric is practical in terms of the capacity of the loom to put in the necessary picks.

The purpose of these tables is to eliminate the need for practically all intermediate computations or graphical techniques previously used for obtaining the solutions to maximum weavability problems. The tables provide immediate solutions to those design parameters that are routinely used by the fabric designer and the textile engineer working on the geometry of textile structures.

b. Scope

This report contains in tabular form the solutions of the equations for cover factor, beta factor, and maximum weavability for the entire practical range of cotton yarn counts, textures and basic weave types.

The Maximum Weavability Table in this report provides solutions to the equations for all of the basic weaves over a cover factor range of from 10 to 32 inclusive at intervals of 1, and over a beta factor range of from 0.5 to 2.0 at intervals of 0.1. This table permits the determination of the maximum weavable constructions for oxford, plain, and 3-, 4-, and 5-harness weaves.

In addition, two tables are presented in order to eliminate the need for computing cover and beta factors: the Cover Factor Table and the Beta Factor Table. These tables provide the solutions to the equations of these parameters for fabric textures of from 11 to 200 yarns per inch and for yarn numbers of from 1/1 to 84/1 equivalent.

2. Theoretical Background and Previous Techniques

The findings of Peirce (5) have been considered basic in the design and development of fabric structures. The equations of Peirce, for the

plain weave, were published in graphical form by Painter (4), and also in nomographic form, by Backer, Adams and Schwarz (1). Finally Love extended Peirce's equations to weaves other than the plain, and developed a series of graphs to simplify the prediction of construction parameters of maximum weavability fabrics (3). This latter report, which describes the derivation of the maximum weavability equations from Peirce's equations, is reproduced as Appendix A. These equations are the basis of the Maximum Weavability Table of this report.

3. Organization of the Tables

a. Cover factor table

Table I("Cover factor in terms of yarn number and texture") provides solutions from the application of the standard and widely used cover factor equation:

$$K = \frac{TPI}{\sqrt{N}}$$

Where: K is either warp cover factor (K_1)
or filling cover factor (K_2)

TPI is threads (or yarns) per inch ["texture" in tables]

N is yarn count ["yarn number" in table]

Practically all textile engineers use this equation, which is basic to the understanding and use of geometric concepts in the design and mechanical manipulation of textile fabrics, as a measure of the relative tightness of the weave of fabrics.

In Table I textures begin at a high of 200 yarns per inch and are listed in decreasing amounts down to 11 yarns per inch; this takes 5 pages. Each sequence of 5 pages gives the cover factors for seven different yarn numbers. To encompass the total range of yarn numbers (from 84 to 1), twelve sequences of 5 pages each are required, or a total of 60 pages.

The textures and yarn numbers in the tables and the computed cover factors are spaced at sufficiently close intervals for most practical design problems; however, if increased precision is desired, fractional yarn numbers and textures may be found by conventional linear interpolation techniques.

b. Beta factor table

Table II ("Beta factor in terms of filling yarn number and warp yarn number") provides solutions from the application of the yarn balance (i.e., beta factor) equation.

$$\beta = \sqrt{\frac{N_1}{N_2}}$$

Where: β is beta factor (yarn balance)

N_1 is warp yarn count ["warp yarn number" in tables]

N_2 is filling yarn count ["filling yarn number" in tables]

While this equation, when used by itself, has less general applicability than the cover factor equation, it is an essential part of the maximum weavability equations solved in Table III.

In Table II warp yarn numbers begin at a high of 100 and are listed in decreasing amounts down to yarn number 1;this takes 3 pages. Each sequence of 3 pages gives the beta factors for seven different filling yarn numbers. To encompass the total range of filling yarn numbers, twelve sequences of 3 pages each are required, or a total of 36 pages.

As in the case of the cover factor table, the warp and filling yarn numbers are spaced sufficiently close for most practical design problems; however, linear interpolation may be used for fractional yarn numbers, if desired.

c. Maximum weavability table

Table III ("Maximum filling cover factor in terms of warp cover factor and beta factor") shows the maximum filling cover factor (K_2) that is theoretically obtainable for given warp cover factor and beta factor. The filling cover factors for the various weaves were obtained by the solutions of the following equations, the derivation of which is given in Appendix A.

PLAIN WEAVE
M = 1

$$\sqrt{1-\left[\frac{\epsilon}{(1+\beta)K_1}\right]^2}+\sqrt{1-\left[\frac{28\beta}{(1+\beta)K_2}\right]^2}=1$$

THREE HARNESS WEAVES
M = 1.5

$$\sqrt{1-\left[\frac{M\left(\frac{30.2}{K_1}-1\right)+1.08}{1.08(1+\beta)}\right]^2}+\sqrt{1-\left[\frac{\left(M\left(\frac{30.2}{K_2}-1\right)+1.08\right)\beta}{1.08(1+\beta)}\right]^2}=1$$

FOUR HARNESS WEAVES
M = 2.0

$$\sqrt{1-\left[\frac{M\left(\frac{31.4}{K_1}-1\right)+1.12}{1.12\ (1+\beta)}\right]^2}+\sqrt{1-\left[\frac{\left(M\left[\frac{31.4}{K_2}-1\right]+1.12\right)\beta}{1.12(1+\beta)}\right]^2}=1$$

FIVE HARNESS WEAVES
M = 2.5

$$\sqrt{1-\left[\frac{M\left(\frac{32.2}{K_1}-1\right)+1.15}{1.15\ (1+\beta)}\right]^2}+\sqrt{1-\left[\frac{\left(M\left[\frac{32.2}{K_2}-1\right]+1.15\right)\beta}{1.15\ (1+\beta)}\right]^2}=1$$

OXFORD WEAVE
$M_1 = 2.0$
$M_2 = 1.0$

$$\sqrt{1-\left[\frac{M_1\left(\frac{31.4}{K_1}-1\right)+1.12}{1.12(1+\beta)}\right]^2}+\sqrt{1-\left[\frac{28\beta}{(1+\beta)K_2}\right]^2}=1$$

M, or Weave Factor, in the above equations is: the number of threads per repeat of weave divided by the number of interlacings per repeat of weave.

In Table III warp cover factors range from 10 to 32, or from 13, 15 or 17 to 32, depending on the weave. For each of five weaves there are two pages of maximum filling cover factors covering beta factors from 0.5 to 2.0, making a total of 10 pages. The maximum filling cover factor values are given to three decimal places. While this is much beyond the precision required for textile design (for which one decimal place is adequate) it was a convenient point by which to program the computations. As in the case of the cover factor and beta factor tables, interpolation may be used for fractional values.

Table III may be read to determine beta or warp cover factors from the filling cover factor. When this is done, it is suggested that the excess decimal places be eliminated to facilitate interpolation. Most of the filling cover factor values given in the table are so close that interpolation may seldom be necessary. For relatively low warp cover factors, interpolation may be desirable. However, since the warp cover

factor is high for most practical textile structures, the need for interpolation usually does not arise.

4. Usefulness of tables

Most of the usefulness of this report will come from the application of Table III to solving maximum weavability problems.

Table III is presented primarily as a solution of the equation for filling cover factor, when warp cover factor and beta factor are known. (It can also be read for a solution when any two elements are given or required, to find the third.)

Perhaps the easiest way to visualize the relationship of these three elements of Table III and how they are obtained is by considering this tabulation:

Element of Table III	Obtainable from	If you have
Filling cover factor	Table I	F yarn number F texture
Warp cover factor	Table I	W yarn number W texture
Beta factor	Table II	W yarn number F yarn number

This tabulation will give some idea of the possibilities of using any yarn number or texture (as in the far right column above) to obtain two of the elements in the far left column (above), and thus to be able to enter Table III.

The textile designer normally has the four constructional factors (listed in the far right column) with which he works: warp texture, filling texture, warp yarn number and filling yarn number. If he knows three of the four fabric variables, it is always a challenge to the designer to calculate the fourth. For instance:

If both yarn numbers but only one texture are known, the other texture for maximum weavability cotton fabrics can be obtained from the table.

If only one yarn number and the yarn balance (beta factor) are known, either texture can be found from a knowledge of the other texture.

If both textures and only one yarn number are known, the other yarn number for maximum weavability can be obtained from the tables by a trial-and-error process.

If the cover factor in the warp direction is known, the corresponding cover factor in the filling direction for a given yarn balance (beta factor) can be obtained.

Or, given a particular construction, it is often necessary for the textile designer to find what is its percentage of maximum weavability. This percentage of maximum weavability can be obtained by using the table.

Also, given a particular construction, the textile designer can determine its practicality. That is, he can determine from the table whether or not it is weavable, without trial weavings.

Given a particular construction, the fabric designer can, by using this table, determine whether it can be tightened to any extent.

Finally, given certain filling parameters, such as yarn size and texture, it is possible to project certain combinations of warp sizes and textures.

b. Solutions for cover factor and beta factor

Tables I (cover factor) and II (beta factor) may be used without any computations to provide exact values for these two commonly used fabric geometry parameters. These solutions have wide applicability in many types of design problems involving cloth cover and weight, and in solving mechanical problems based on Peircian geometry.

5. Examples of use of tables

a. Using Cover Factor Table

Below are given some specific problems using Table I ("Cover factor in terms of yarn number and texture")

1) Given: ends and yarn number. To find: warp cover factor
Problem: A sateen has 129 ends of 31/1 yarn
What is the warp cover factor?

Solution:
In Table I, find the "yarn number" at top of column on page 83; for this problem it is 31
Texture is given under "texture" column at left; for this problem texture is 129
Column 31 and row 129 intersect at 23.169; this is the warp cover factor required.

2) Given: picks and yarn number. To find: filling cover factor

Problem: A poplin is woven with 80 picks of 40/2 cotton yarn What is the filling cover factor?

Solution:

First, since the tables are based on singles equivalent yarn number, convert 40/2 to 20/1

In Table I, find the "yarn number" at top of column on page 95; for this problem it is 20

"Texture" is given under the far left column; for this problem texture is 80

Column 20 and row 80 intersect at 17.889; this is the filling cover factor required

3) Given: warp yarn number, a desired warp cover factor. To find: ends required

Problem: It is desired to use a 72/2 warp yarn in a twill fabric to obtain a warp cover factor of approximately 26.0 How many ends per inch will be needed in the finished fabric?

Solution:

First, since the tables are based on singles equivalent yarn number, convert 72/2 to 36/1

In Table I, find the "yarn number" at top of column on page 77; for this problem it is 36

Move down under yarn number 36 until "cover factor" 26.00 is reached

By following along this row to the far left column a "texture" of 156 is found. That is, 156 ends per inch will be needed.

4) Given: ends and yarn numbers for 2 fabrics. To find: which cover factor is greater

Problem: Which fabric will provide a greater warp cover factor: an oxford with 120 ends of 16/1, or one with 125 ends of 17/1?

Solution:

The procedure is to find in Table I the cover factor for each fabric as in (1) above, and compare them.

To find the cover factor for first fabric, find "yarn number" column 16 on page 93; find "texture" (far left column) of 120; where column 16 and row 120 intersect we get a cover factor of 30.000

Similarly, for "yarn number" 17, the "texture" (far left column) of 125 gives (where they intersect) cover factor of 30.317

Thus the fabric with the 17/1 yarn has the greater cover factor

b. Using Beta Factor Table

Below are some typical problems using Table II ("Beta factor in terms of filling yarn number and warp yarn number")

1) Given: filling yarn number and warp yarn number. To find: beta factor

Problem: A sateen has a 23/1 yarn in the warp and a 12/1 yarn in the filling
What is the yarn balance (beta factor)?

Solution:
In Table II, find the "filling yarn number" at top of column on page 141; for this problem: 12
Find "warp yarn number" in far left column: 23
Column 12 and row 23 intersect at 1.384, which is beta factor.

2) Given: warp yarn number, desirable beta factor. To find: filling yarn number required

Problem: We desire a yarn balance (beta factor) of 1.3 in a crowfoot fabric using an 80/2 warp yarn
What size 2-ply yarn will be used for the filling?

Solution:
First (since tables are based on singles) convert 80/2 to 40/1
In Table II, "warp yarn number" 40 (far left column) occurs 12 times. Examine each row of values of 40 until a beta factor close to 1.3 is found
For "warp yarn number" 40, a beta factor of 1.291 occurs on page134 under (top column heading) "filling yarn number" 24
Reconvert this filling yarn number from 24/1 to 48/2

3) Given: For Fabric X: beta factor, warp yarn number and ends; for Fabric Y: beta factor and warp yarn number
To find: how many ends must be put into Fabric Y to obtain same warp cover factor as Fabric X

Problem: Two plain-weave fabrics are available which have yarn balances (beta factors) of 1.0 (Fabric X) and 1.1 (Fabric Y). If the warp yarns in each fabric are 30.0 and Fabric X has 120 ends in the warp, how many ends must be put into the Fabric Y to obtain the same warp cover factor?

Solution:
Step 1. Find filling yarn numbers in Table II for the two fabrics, as in b (2) above.
Look up the various rows for "warp yarn number" 30 (far left column in Table II),until you find the beta factor value nearest to 1.0 (this is found on page 132 to be 30), and nearest to 1.1 (this is found on page 135 to be 25).
Step 2. Find "warp cover factors" in Table I, for Fabric X, as in a (1). This is the intersection of "yarn number" 30, given "texture" of 120, or 21.909. (page 83).
Step 3. Find number of ends required to provide this same cover factor (21.9) for Fabric Y (beta factor 1.1)
Step 1 gave filling yarn number for Fabric Y as 25.
In Table I find column 25 "filling yarn number", follow down to cover factor nearest to 21.909, which is 22.000 (page 89).

Move left along this row to find "texture" at far left: 110
Therefore: 110 ends in the fabric having a beta factor of 1.1 will provide the same cover as 120 ends in the fabric having a beta factor of 1.0

c. Using Maximum Weavability Table

Below are some typical problems using Table III("Maximum filling cover factor in terms of warp cover factor and beta factor"). It is recommended that the engineer familiarize himself with the use of Tables I and II before attempting to use Table III. The Cover Factor Table and the Beta Factor Table must be used each time Table III is used.

1) Given: filling yarn number, warp yarn number, warp texture and weave
To find: number of picks for maximum weavable construction
Problem: What are the maximum number of picks of yarn number 19/1 that can be woven into a poplin having 106 ends of 40/2 yarn?
Solution:
Step 1. Find warp cover factor, as in example a (1) above
First convert 40/2 to 20/1 (tables are for singles)
In Table I, the intersection of "yarn number" column 20 (top) and "texture" 106 (far left) given "warp cover factor" of 23.702 (page 94)
Step 2. Find beta factor for yarns, as in example b (1) above
In Table II, the intersection of column 19 ("Filling yarn number" at top) and row 20 ("Warp yarn number", far left) gives beta factor of 1.026 (page 138)
Step 3. Find maximum filling cover factor
In Table III-A, intersection of "beta factor" (top column), of 1.0 (closest value to 1.026) and row 24 "warp cover factor" (far left) gives "maximum filling cover factor" of 14.254* (page 148)
Step 4. Find number of picks that would provide a cover factor of 14.3 when 19/1 yarns are used in filling.
In Table I, under column 19 ("yarn number", at top) "cover factor" of 14.224 is nearest. (page 95). Move along row to left to find required filling "texture" under texture column: it is 62.

* If it is desired to obtain increased precision, interpolation may be used with the fractional beta factor and the fractional cover factor obtained from Tables I and II, respectively. In this particular problem, the interpolation would be of no value with respect to warp cover factor since, at a warp cover factor of 23, the equivalent filling cover factor would be 14.309, which even at three significant figures is still the 14.3 obtained above. Interpolation for the beta value of 1.026 would increase the maximum filling cover factor to 14.416, or 14.4 in three significant figures. Accordingly, it is suggested that interpolation be ignored for first approximations.

Thus: the maximum number of picks that could be used in the initial fabric is 62.*

2) To determine percentage of maximum weavability

Problem: A Type III wind-resistant oxford has a specified texture of 136 by 46. If a 40/2 warp yarn is available - what percent of maximum weavability will be obtained if we use a 12/1 filling?

Solution:

First convert 40/2 to 20/1

Step 1: Find warp cover factor, as in Example a (1)
In Table I, intersection of yarn number 20 (top) and texture 136 (far left) gives a warp cover factor of 30.411 (page 93)

Step 2. Find filling cover factor, as in example a (2)
In Table I, intersection of yarn number 12 and texture 46 gives a filling cover factor of 13.279 (page 100)

Step 3. Find beta factor as in example b (1)
In Table II, intersection of filling yarn number 12 and warp yarn number 20 gives beta factor of 1.291 (page 141)

Step 4. Find maximum possible filling cover factor
In Table III-E, at intersection of beta factor 1.3 (top) and warp cover factor (far left), 30: 15.937 (page 157)

Step 5. To obtain percent maximum weavability:
Divide actual filling cover factor (13.3) by maximum filling cover factor (15.9) to obtain 83.6 as percent of maximum weavability.

3) To determine weavability or practicality of a given loom construction

Problem: Is a sateen fabric weavable if it has 129 ends of 31/1 yarn and 94 picks of 14/1?

Solution:

Step 1. Find warp cover and filling cover factors
In Table I, intersection of yarn number 31 (top) and texture 129 (far left) gives warp cover factor of 23.169
Similarly, intersection of yarn number 14 (top) and texture 94 (left) gives filling cover factor of 25.123

Step 2. Find beta factor
In Table II intersection of filling yarn number 14 (top) and warp yarn number 31 (far left) gives beta factor of 1.488

Step 3. Find maximum filling cover factor
In Table III-D intersection of beta factor 1.5 (top) and warp cover factor 23 (far left) gives maximum filling cover factor of 25.514
Since the actual filling cover factor is less than the

* If the interpolated value of 14.416 has been used, the maximum number of picks would be 63. This difference is considered to be non-significant for the order of precision characteristic of the basic equations upon which these tables are based.

theoretical maximum, the fabric should be weavable.

Step 4. Find the maximum number of picks for 14/1 yarn

In Table I under 14 yarn number, it is indicated that for cover factor 25.5, 95 picks are equivalent.

Thus, on a theoretical basis, it should be possible to add an additional pick to the fabric.

6. Basic assumptions and limitations of the tables

a. Basic assumptions

Two assumptions were made in developing the equations that led to the formulation of these tables:

1. The yarn compression in a fabric woven to maximum tightness produces a change in the shape of the yarn section but does not alter the fiber-packing density.

2. Complete flattening takes place in that half of the yarn that is in contact with a neighboring yarn under a single float (see Appendix A.)

For all practical purposes, these assumptions produce only minimal errors and thus the tables are completely suitable for first-order approximations in fabric design. For a series of 13 ducks analyzed by Dickson (2) the average deviation between the filling limits computed from the equations that form the basis for these tables and those observed in actual fabrics was only 1.18 cover factor units. Of the 13 ducks, 12 actually exceeded the theoretical limit, which means that, as a first approximation in design, only 1 of the 13 fabrics would have been impractical to weave. This fabric was only 0.3 cover factor units higher than that actually obtained in the loom.

b. Limitations of the Tables

In using the tables, one must keep in mind the following limitations:

1. The yarn numbers given are applicable to the conventional indirect yarn numbering system used for cotton, woolens and worsteds. The tables are designed primarily for cotton fabrics. For fabrics other than cotton, the maximum weavability table (Table III) cannot be used without some modification. For those now working with fibers other than cotton, the "all-fiber" computations worked out by Dickson (2) provide a means of converting data on nylon, for example, to cotton counts and (after correcting for density), thus using the tables in this report for design studies involving other fibers. It is hoped that similar sets of tables will later be developed for use with woolen, worsted, and man-made fiber systems.

2. The yarn numbers in the tables are singles equivalent. If, for example, a 20/2 or 60/3 yarn number is involved, it must first be converted to singles equivalent. The 20/2 would be a 10/1, and the 10 column of the table would be used; the 60/3 would become a 20/1, and the 20 column of the table used.

3. It will be noted that the cover factor values of some pages go as high as an unrealistic 75. While such high values are impossible, they were retained to facilitate the programming of the computer, which printed the "master" tables reproduced in this report.

4. In using the tables, it is suggested that interpolation be avoided on the first attempt to arrive at a design. It is usually easier to locate the values for parameters just below and above the exact value and then determine whether the difference warrants any further precision. In most problems it is only a question between a single pick or end or a fractional yarn count; the overall validity of the equations, considering the assumptions that had to be made in deriving them, is no better than this.

5. It must be stressed again that, while the tables provide approximations which are extremely useful in obtaining orders of magnitude for design problems, the actual loom conditions as well as other variables will determine the exact final values.

GRAPHICAL RELATIONSHIPS IN CLOTH GEOMETRY FOR PLAIN, TWILL, AND SATEEN WEAVES

1. Introduction

The subject of fabric geometry was formalized in the comprehensive mathematical analyses of F. T. Peirce * in 1937. Surprisingly little use has been made of Peirce's work in the practical field of cloth design during the past 17 years. This delay has been due in part to the mathematical complexities inherent in the relationships between such cloth parameters as threads per inch, yarn count, and crimp. Peirce attempted to alleviate this condition by furnishing extensive tables relating the variables of fabric construction and by proposing both models and graphs to shorten the computations necessary for the design of new materials. Recently extensive graphical methods have been proposed ** with a view to eliminating extended calculations and lengthy interpolations from Peirce's tables. A parallel set of graphical techniques has been developed in the Textile Laboratories of the Quartermaster Corps and has found considerable use during the past five years. It is the purpose of this paper to make these additional useful graphical tools available to the practicing fabric designer.

In the course of applying Peirce's theories to the design of various fabrics, it was found both necessary and convenient to extend the range of the diagrams presented for plain weave fabrics and to evaluate their functions in additional weaves. Although Peirce mentioned the effect of weave on maximum setting, the importance of this factor on the physical behavior of a fabric indicated a need for further development. Accordingly, an extensive series of calculations was made in order to provide a graphical presentation of the effect of short float weaves on the tightness of a fabric.

2. Geometry of the plain weave

The first case considered was the plain weave in which the ratio (β) of filling yarn diameter to warp yarn diameter varied significantly. The practical question

*In "The geometry of cloth structure," Journal Textile Institute 28, T45, (1937)
**By E. V. Painter in "Mechanics of elastic performance of textile materials, VIII Graphical analysis of fabric geometry" in Textile Research Journal 22, 153 (1952).

asked in the design of many military fabrics in the past 10 years has been, "If the warp cover factor * is prescribed for reasons of water or wind resistance, what is the maximum number of picks weavable in such a fabric?" Peirce has indicated that for closest plain weaves

$$\sqrt{1 - \left(\frac{p_1}{D}\right)^2} + \sqrt{1 - \left(\frac{p_2}{D}\right)^2} = 1 , \qquad (1)$$

and that

$$K_1 = \frac{28}{1 + \beta} \div \frac{p_1}{D}; \qquad (2)$$

$$K_2 = \frac{28\beta}{1 + \beta} \div \frac{p_2}{D}, \qquad (3)$$

where p_1, p_2 are the spacings in inches between warp and filling threads; K_1, K_2 are warp and filling cover factors; β is the ratio of filling to warp diameters; and D is the sum of warp and filling yarn diameters in inches. By combining the above equations one obtains the expression:

$$\sqrt{1 - \left[\frac{28}{(1 + \beta) K_1}\right]^2} + \sqrt{1 - \left[\frac{28\beta}{(1 + \beta) K_2}\right]^2} = 1 , \qquad (4)$$

*Defined by Peirce (for the inverse yarn-numbering system) as the ratio of the threads per inch to the square root of the yarn number.

indicative of the relationship between K_1, K_2, and β for fabrics jammed in both directions. It is now evident that the answer to the above stated question may be determined uniquely, provided that the value β is specified. Peirce took the case of $\beta = 1$ and plotted K_1 versus K_2 for the closest plain weave constructions. It has been found necessary in many Quartermaster studies to work with β values differing significantly from $\beta = 1$ and so an extension of Peirce's graph has been made. This extension is presented in Figure 1. *

A corollary to the use of Figure 1, indicated above, is the quick graphical answer to the question, "What is the relative tightness in warp and filling direction in a given fabric?" Warp tightness may be expressed as the ratio of actual warp cover factor to maximum warp cover factor, as determined from Figure 1, when the filling cover factor and the ratio of yarn diameters are specified. Likewise the relative filling tightness is expressed as the ratio of actual filling cover factor to maximum filling cover factor as determined from Figure 1. The overall value of tightness, useful in studies of the mechanical properties of fabrics, is expressed as:

$$\text{tightness} = \frac{\text{sum of actual warp and filling cover factors}}{\text{sum of theoretically maximum cover factors}} \qquad (5)$$

The maximum cover factors for other yarns in addition to cotton are given for the reader's convenience in the legend of Figure 1 (and also of Figures 2 to 5 inclusive). These cover factors have been calculated from the specific volume of the material, v, based on Peirce's formula

$$v = 1.021 y N d^2 \quad , \qquad (6)$$

where N is the number of units (hanks) of length; y, yards in a pound of yarn of diameter d, in inches. Peirce assumed a constant value of 1.1 for the apparent

*Figures are at the end of this report

specific volume of the cotton yarn under the compression of the weave structure. So that comparisons can be made among the various fibers, v is here replaced by the inverse product of the specific gravity of the fiber (ψ) and the yarn packing coefficient (ϕ). Thus for the inverse yarn numbering system equation (6) becomes:

$$\frac{1}{d} = \sqrt{1.021 y N_i \psi \phi} \quad , \tag{7}$$

and for the direct system

$$\frac{1}{d} = \sqrt{1.021 y / N_d \psi \phi} \quad , \tag{8}$$

where d is again expressed in inches while y is expressed in yards per pound. For the direct denier system y = 4,464,528 yards per pound. The pack coefficient, ϕ, has been estimated to be approximately 0.6.

3. Geometry of other weaves

When other than plain weaves are studied the quantities p_1 and p_2 of equation (1) apply to the local spacings between yarns at the interlacings of warp and filling. The local spacings between warp and filling at points of no interlacing, that is, at float locations, will in general be less than the local spacing at points of interlacing. Since quantities K_1 and K_2 represent average cover factors, relationships (2) and (3) must be altered to account for the weave factor and the degree of yarn flattening and/or overriding which takes place in other than plain weaves. Weave factor, M, is defined as:

$$M = \frac{\text{Number of threads per repeat of weave}}{\text{Number of interlacings per repeat of weave}} \quad . \tag{9}$$

Thus, M = 1 characterizes the plain weave; M = 1.5, a 2/1 twill; M = 2, a 2/2 twill, a 3/1 twill, a 4-harness satin or the warp yarns of an oxford weave; M = 2.5 a 3/2 twill, a 4/1 twill, or a 5-harness satin. If the degree of flattening is over-

looked for the moment, the local spacing between warp yarns at the interlacing of warp and filling can be shown to equal

$$p_1 = Mp_{a1} - (M - 1)d_{oa1} \quad , \tag{10}$$

where d_{oa1} is the original average lateral diameter of the warp yarn. If lateral compression is now considered, the expression for the local spacing, p_1, is somewhat modified by the introduction of d_{ca1}, the new average lateral diameter of the warp yarns. The new diameter d_{ca1} averages both compressed and uncompressed lateral diameters pictured below for several different weave repeats.

$$p_1 = M(p_{a1} - d_{ca1}) + d_{oa1} \quad . \tag{11}$$

When yarns of average twist or softness are woven in fabrics of other than plain weave, it has often been observed that maximum weavable cover factors exceed the value 28. The reason for this becomes evident in microscopic examination of fabric cross sections which show considerable lateral compression in yarns beneath the weave floats. The extent of this compression will, of course, vary with the twist of the yarn, the fiber cross sections, and the actual transverse compression between yarns. For purposes of computation we may assume (1) that the yarn compression in a fabric woven to maximum tightness produces a change in the shape of the yarn section, but does not alter the fiber packing density; and (2) that complete flattening takes place in that half of the yarn which contacts a neighboring yarn under a single float, i. e., that the original semicircle of the yarn half section becomes a rectangle after compression. This definition of beneath-float compression depicted in the diagram satisfies the condition of actual fabric geometry observed in numerous practical instances. Since fiber packing densities are unaltered during compression, it follows that the lateral half width of the compressed yarn changes from $d/2$ to $\pi d/8$, while the vertical dimension remains unchanged. As seen in A and B of the diagram, the lateral width of a yarn flattened on one side only becomes $d/2\,(1 + \pi/4)$,

while the entire lateral width of a yarn flattened on both sides is reduced from d to $\pi d/4$.

In the case of a filling float passing over two warp yarns, the horizontal width of all warp yarns per repeat is seen in A of the diagram to be $2.78\ d_{oa_1}$ where d_{oa_1} is the average diameter of the original yarns, subscript a being the average condition computed for the weave repeat, subscript o the original uncompressed state and subscript 1 indicating warp. The average compressed warp diameter calculated for the repeat of the 2/1 weave is $2.78\ d_{oa_1}/3$. The warp cover factor is by definition,

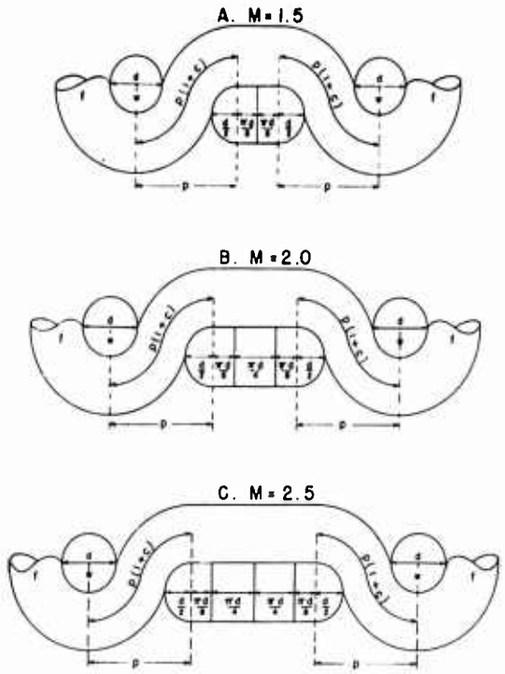

DIAGRAM: YARN COMPRESSION BETWEEN THE FLOAT.

$$K_1 = \frac{\text{Threads per inch}}{\sqrt{\text{Warp count}}} = \frac{\text{TPI}}{\sqrt{N_1}} \qquad (12)$$

Peirce has shown in reference mentioned at the beginning of this report, that for cotton yarns under compression

$$d = \frac{1}{28\sqrt{N}} \quad . \qquad (13)$$

The maximum average warp cover factor will occur when adjacent ends are in contact throughout the repeat and this condition is observed when the filling crimp is reduced to zero and the average spacing between ends just equals the average

compressed warp diameters.

$$K_{a1}\,(\text{máx.}) = \frac{TPI_{a1}}{\sqrt{N_{a1}}} = \frac{28\,d_{oa1}}{p_{a1}} = \frac{28\,d_{oa1}}{d_{ca1}}\ , \tag{14}$$

and since

$$d_{ca1} = (2.78/3)\,d_{oa1} = 0.93\,d_{oa1}\ , \tag{15}$$

$$K_{a1}\,(\text{max.}) = \frac{(3)\,(28)\,d_{oa1}}{2.78\,d_{oa1}} = 30.2\ . \tag{16}$$

We can now express p_1, the local warp spacing in terms of the fabric scale unit, D, the sum of vertical diameters in warp and filling. Recall that

$$D = d_{oa1} + d_{oa2} = d_{oa1}\,(1 + \beta)\ ; \tag{17}$$

from equation (15)

$$D = 1.08\,d_{ca1}\,(1 + \beta)\ , \tag{18}$$

whence

$$\frac{p_1}{D} = \frac{M\,(p_{a1} - d_{ca1}) + d_{oa1}}{1.08\,d_{ca1}\,(1 + \beta)}\ , \tag{19}$$

$$\frac{p_1}{D} = M\,\frac{\left(\frac{30.2}{K_{a1}} - 1\right) + 1.08}{1.08\,(1 + \beta)} \tag{20}$$

since from equation (14)

$$K_{a1} = \frac{28\,d_{oa1}}{P_{a1}} = \frac{28\,(1.08)\,d_{ca1}}{P_{a1}} = \frac{30.2\,d_{ca1}}{P_{a1}}\ . \tag{21}$$

Corresponding to equation (20) we have

$$\frac{P_2}{D} = \frac{\left[M \left(\frac{30.2}{K_{a2}} - 1 \right) + 1.08 \right] \beta}{1.08 (1 + \beta)} \qquad (22)$$

Substituting equations (20) and (22) in equation (1), one arrives at

$$\sqrt{1 - \left[\frac{M \left(\frac{30.2}{K_{a1}} - 1 \right) + 1.08}{1.08 (1 + \beta)} \right]^2} + \sqrt{1 - \left[\frac{\left(M \left[\frac{30.2}{K_{a2}} - 1 \right] + 1.08 \right) \beta}{1.08 (1 + \beta)} \right]^2} = 1. \qquad (23)$$

Equation (23) serves as the principal basis for construction of Figure 2 in which the relationship between K_{a1} and K_{a2} and β is presented graphically. Comparison of Figures 2 and 1 for given values of warp cover factor and β shows the filling packing limit for the twill weave (M = 1.5) to be much higher than for the plain weave. Similarly, it can be shown that for given values of K_{a1}, K_{a2}, and β the relative tightness one obtains in a plain weave is much higher than that in a twill weave. These qualitative facts are known to the textile technologist. The value of the graphs lies in the quantitative values which may now be readily determined.

In the case of a 3/1 (or a 2/2) twill, i. e., when M = 2.0, the central yarns beneath the float will be compressed to the width $\pi d/4$ as seen in B of the diagram. The average compressed diameter now becomes

$$d_{ca1} = 3.57 d_{oa1}/4 = 0.89 d_{oa1} , \qquad (24)$$

or

$$d_{oa1} = 1.12 d_{ca1} . \qquad (25)$$

It follows that

$$K_{a1} = \frac{TPI}{\sqrt{N}} = \frac{28 d_{oa1}}{P_{a1}} = \frac{31.4 d_{ca1}}{P_{a1}} , \qquad (26)$$

whence

$$\frac{P_1}{D} = \frac{M\left(\frac{31.4}{K_1} - 1\right) + 1.12}{1.12\,(1+\beta)} \quad ; \tag{27}$$

$$\frac{P_2}{D} = \frac{\left[M\left(\frac{31.4}{K_2} - 1\right) + 1.12\right]\beta}{1.12\,(1+\beta)} \quad . \tag{28}$$

From equations (27) and (28) the relationship corresponding to equation (23) leads to the graphical presentation of Figure 3 for 3/1 or 2/2 fabrics, i. e., M = 2.0. In the cases where M = 2.5 we may have either a 4/1 or a 3/2 weave. From C of the diagram the average compressed diameter for M = 2.5 is seen to be:

$$d_{ca1} = 0.87 d_{oa1} \tag{29}$$

or

$$d_{oa1} = 1.15 d_{ca1} \quad , \tag{30}$$

whence

$$K_{a1} = \frac{28(1.15)d_{ca1}}{P_{a1}} = \frac{32.2 d_{ca1}}{P_{a1}} \tag{31}$$

and

$$\frac{P_1}{D} = \frac{M\left(\frac{32.2}{K_1} - 1\right) + 1.15}{1.15\,(1+\beta)} \tag{32}$$

$$\frac{P_2}{D} = \frac{\left[M\left(\frac{32.2}{K_2} - 1\right) + 1.15\right]\beta}{1.15\,(1+\beta)} \tag{33}$$

Substitution of equations (32) and (33) in equation (1) leads to the geometric relationship between K_{a_1} and K_{a_2} for maximum weavable fabrics of a 4/1 or 3/2 twill construction (including sateens). This function is plotted in Figure 4. Again, comparison of Figures 2, 3 and 4 with the curves relating K_1 and K_2 for the plain weave (Figure 1) reveals that increasingly greater filling packing limits (for any fixed warp cover factor) occur at higher weave factors. Conversely, if filling covers are arbitrarily fixed, greater warp packing is possible at higher weave factors. Finally, when β, K_1, and K_2 are specified, the relative tightness of a given weave decreases as M increases.

There is little point in extending the indicated modifications of equations (2) and (3) to the weave factors exceeding $M = 2.5$ since it is unlikely that the simple geometric assumptions indicated in the diagram are met for floats longer than 4-cross yarns. Indeed, in applying the relationships presented in Figure 4 for the weave factor 2.5, the technologist must insure compliance of the actual structure with the geometric assumption of lateral compression.

To make the graphical solutions outlined above generally applicable, we must include a sample of those constructions which possess different weave factors in the warp and filling directions. The most common material of this category is the oxford weave in which two warp yarns interlace as one in an otherwise plain weave, resulting in weave factors, $M_1 = 2.0$ and $M_2 = 1.0$. To obtain a relationship between K_1, K_2, and β for an oxford weave one must substitute equations (27) and (3) for p_1 and p_2 respectively in equation (1). The result of this substitution is plotted in Figure 5.

This discussion of fabric geometry thus far has been concerned with the projected cover of warp and filling yarns and with the relative tightness of each yarn system. Cover factors, it has been pointed out, are of primary interest in studies of the permeability of fabrics to air and water. Tightness factors, on the other hand, relate to a wide variety of mechanical fabric properties including wear resistance, flexibility, drape, and dimensional stability. Note, however, that cover

and tightness factors pertain principally to the two-dimensional structure of the fabric. To round out the consideration of fabric properties, it is essential to deal with the third fabric dimension, that of thickness, or "wave height" of the yarn systems. Peirce has pointed out that the thickness of a fabric equals the sum of the wave height and diameter of warp or filling yarns, whichever sum is larger. The thickness of fabric structures is directly related to their insulating qualities and their cushioning or softness characteristics. On the other hand, the difference between the wave height and diameter sum for warp and filling systems determines the absolute projection of one yarn system above the other at the fabric surface. This projection significantly influences the appearance and the wearing qualities of the fabric.

Peirce has shown the approximate relationship between wave height, h, the fractional crimp, c, and the yarn spacings, p,

$$h_1 = 1.36\, p_2 \sqrt{c_1} \quad , \tag{34}$$

to hold over a wide range of fabric constructions. It must be noted, however, that the values of crimp and thread spacings in equation (34) apply to the plain weave or to the unit cell of the twill weave where interlacing takes place. Peirce plotted equation (34) in terms of h_1/D and p_2/D, as illustrated in the lower left hand corner of Figure 6 (the radiating lines). The curve at the extreme left represents the condition of maximum weavability, and is plotted from the requirement

$$\cos \theta_1 + \cos \theta_2 = 1 \quad , \tag{35}$$

where θ is the maximum inclination of a given yarn to the fiber plane. Recall the additional requirement for jamming in both warp and filling direction, i. e.,

$$h_1/D = \cos \Delta_1 \quad . \tag{36}$$

and

$$\frac{p_2}{D} = \sin \Delta_2 = \sqrt{1 - \cos^2 \Delta_2} \quad , \tag{37}$$

where Δ_1 is the acute angle formed when a line perpendicular to the plane of the fabric intersects a line joining the centers of two warp yarns separated by a filling yarn and Δ_2 is the same angle for the opposite set of yarns. These angles

are quantitatively identical to Peirce's θ_2 and θ_1 respectively (equation 35). Moreover, if one considers the condition of maximum weavability, it can be shown that the arcs described by the opposing threads of the unit cell (see diagram) provide crimp values more accurately represented on the curve of maximum weavability by

$$c_1 = \frac{L_1/D}{p_2/D} - 1 = \frac{\Delta_2 \text{ radians}}{\sin \Delta_2} - 1 \qquad (38)$$

than by equation (34). Crimp values plotted from (34) and (38) are combined in Figure 6 to form almost straight lines.

To extend the relationships between h_1 and p_2 to twill weaves, it is necessary to employ C_1 (pertaining to the entire twill fabric) as a variable, not simply c_1 which pertains to the interlacing unit cell. This modification is essential since the weave designer customarily varies C_1 by appropriately setting his reed width, warp take-ups and subsequent tentering widths. C_1 for the entire fabric is defined as the excess of actual length of the yarn axis as it lies in the fabric, over its length as projected onto the horizontal plane. If one takes a filling section corresponding to the warp cross sectional view of A of the diagram, it can be shown that the projected length of the warp yarn, L_p, in a 2/1 twill is

$$L_{p1} = 2p_2 + 0.785d_2 \ , \qquad (39)$$

while the actual length L_t is

$$L_{t1} = 2p_2 (1 + c) + 0.785d_2 \ , \qquad (40)$$

whence the fractional warp crimp for the entire weave is

$$C_1 = \frac{2p_2c_1}{2p_2 + 0.785d_2} \ , \qquad (41)$$

or

$$C_1 = \frac{2\,(p_2/D)\,c_1}{2\,(p_2/D) + [0.785\,\beta/(1+\beta)]}, \qquad (42)$$

since

$$D = d_1 + d_2 = d_2\left(\frac{1}{\beta} + 1\right) = d_2\left[\frac{(1+\beta)}{\beta}\right]. \qquad (43)$$

It follows from the above derivation that equation (42) relates C_1 to c_1 under conditions of maximum weavability and therefore the value of p_2/D in equation (42) must be obtained from equation (22). However, when moderately tight 2/1 fabrics are dealt with, equation (42) still holds with reasonable accuracy provided the yarns beneath each float are in contact with one another. In such fabrics the yarns are no longer compressed and the factor 0.785 in equation (42) is replaced by unity, and

$$C_1 = \frac{2\,(p_2/D)\,c_1}{2\,(p_2/D) + [\beta/(1+\beta)]}. \qquad (44)$$

In open fabrics the crimp values (both for the plain weave unit cell and for the 2/1 twill fabric as a whole) will be small. The form of equation (42) indicates the C_1 will always be smaller than c_1; i. e., c_1 may be considered to be the maximum limit of C_1. In Figure 6, the radiating c_1 lines have been relabeled with the appropriate values of C_1 calculated from equation (42) for 3/1 constructions of maximum tightness and for β's of 0.5, 1, and 2. In this way a graphical relationship is established among h_1/D, p_2/D, and C_1 with greatest accuracy in the region of maximum weavability.

Following the procedure described above we may use the geometric assumptions of B of the diagram (reversing subscripts 1 and 2 so that the view given will represent a section at right angles to that of the figure) to deduce the relationship

$$C_1 = \frac{(p_2/D)\ c_1}{(p_2/D) + [0.785\,\beta/(1+\beta)]} \qquad (45)$$

for the weave factor M = 2.0, i. e., for 3/1 or 2/2 weaves. Cloth crimps based on equation (45) have been calculated for fabrics of maximum tightness at β values of 0.5, 1 and 2 and these are indicated as secondary labels on the radiating lines of Figure 6. Finally, the filling section corresponding to the view shown in C of the diagram furnished the geometric constants leading to the relationship

$$C_1 = \frac{2\,(p_2/D)\,c_1}{2\,(p_2/D) + [2.355\,\beta/(1+\beta)]} \qquad (46)$$

for 4/1 or 3/2 fabrics corresponding to a weave factor M = 2.5. Values of C_1 from equation (46) are likewise indicated in Figure 6 for M = 2.5 and β's of 0.5,1 and 2.

It should be noted that equations (42), (45), and (46) deal with total warp crimp. To calculate filling crimp, these same equations may be used, provided the β over the $(1 + \beta)$ is eliminated. A simpler method of determining filling crimp for the fabric from equations(42), (45), and (46) is to use β' instead of β, where β' is the reciprocal of β. This device permits use of Figure 6 for determination of <u>both</u> warp and filling crimps necessary in a wide range of weaves to achieve desired values of wave height and thread spacings.

APPENDIX B

COMPUTER PROGRAM FOR SOLUTION OF MAXIMUM WEAVABILITY EQUATIONS

1. Introduction

The computer program summarized in this report was written with the intent of tabling the five graphs found in the report reprinted as Appendix A ("Graphical relationships in cloth geometry for plain, twill, and sateen weaves").

The program was a result of a group effort by the Computer Branch, of which Mr. John M. Lawler is chief. Major contributions were made by Messrs David Gracia and George H. Haines, Jr. Also, the Computer Branch would like to acknowledge the helpful suggestions of Mr. James Mills, Aerial Delivery Equipment Division.

2. Program description

a. General

The program finds values of K_2 which satisfy three equations. These equations are:

1. $$\sqrt{1-\left[\frac{28}{(1+\beta)K_1}\right]^2} + \sqrt{1-\left[\frac{28\beta}{(1+\beta)K_2}\right]^2} = 1$$

2. $$\sqrt{1-\left[\frac{M\left(\frac{C_1}{K_1}-1\right)+Z}{Z(1+\beta)}\right]^2} + \sqrt{1-\left[\frac{\left(M\left(\frac{C_1}{K_2}-1\right)+Z\right)\beta}{Z(1+\beta)}\right]^2} = 1$$

3. $$\sqrt{1-\left[\frac{M_1\left(\frac{31.4}{K_1}-1\right)+1.12}{1.12(1+\beta)}\right]^2} + \sqrt{1-\left[\frac{28\beta}{(1+\beta)K_2}\right]^2} = 1$$

The range of variables is:

(β from 0.5 to 2.0 inclusive - intervals of .1

(K_1) from 8 to 32 inclusive - intervals of 1.0

In addition, for equation (2) there are three sets of conditions:

(2a) M = 1.5, C_1 = 30.2 Z = 1.08

(2b) M = 2.0, C_1 = 31.4 Z = 1.12

(2c) M = 2.5, C_1 = 32.2 Z = 1.15

Before writing the program, these equations were analytically solved for K_2 as a function of β and K_1. Thus, the program calculates K_2 directly, given parameter values, and values of β and K_1. The analytical solution of the equations is discussed in a Note at the end of this Appendix. The program automatically halts when answers become complex numbers, and goes on to the next table. Only answers which are real numbers are printed.

b. Functional

Not applicable

3. Operating instructions

a. Deck make-up

There are three programs, one for each equation. The programs are in WIZ, and must, therefore, be compiled before being run. The object program followed by one data card (for the equation [2] program) is placed behind Wizpac, and a normal WIZ load executed. The answers should follow. For the equation (1) or equation (3) programs there is no data card.

b. Tape drives

Not applicable

c. Input

The input for Program II consists of one card with values for C_1, Z and M punched on it in that order. The values must obey the rules for WIZ data cards. There are no data cards read by Program I or Program III.

d. Data display

The output consists of a series of tables. There is one table for each value of ; following the given B are printed the given value of K_1 and, to the right of K_1, the calculated K_2. One table is printed on each sheet of paper.

4. Flow charts

Program I:

1. Initialize B1 = 0.5; K1 = 32, C1 = 28
2. Print Headings
3. Compute K2 and output it
4. Go on to next table when present table is computed

Program II:

1. Initialize B and K1
2. Read C1, Z, M
3. Print Headings
4. $FA = (M(C1/K1 - 1) + Z)/(Z(1 + B)^2)$
5. $FB = 1 - FA$
6. $FC = 2/FB$
7. $FG = FA + FC - 1$
8. $K_2 = (B)(M)(C1)/(FD)(Z)(1+B)-(B)(Z)+(B)(M)$
9. Print value of K1 and K2
10. Step K1
11. Go on to next table when ready
12. Halt when all tables are computed

5. Variable Dictionary

K_1 = K1

K_2 = K2

M = M

Z = Z

C_1 = C1

β = B

FA, FB, etc = interval working variables

NOTE

Below is briefly sketched the nature of the solution to these equations:

$$\sqrt{1+\left[\frac{28}{(1+\beta)K_1}\right]^2} + \sqrt{1-\left[\frac{28\beta}{(1+\beta)K_2}\right]^2} = 1$$

let $A = [28/(1+\beta)K_1]$

$C = [28\beta/(1+\beta)K_2]$

$$\sqrt{1-C^2} = 1 - \sqrt{1+A^2}$$

Square both sides

$$1 - C^2 = 1 - 2\sqrt{1+A^2} + 1+A^2$$

Cancel the ones

$$-C^2 = 1 - 2\sqrt{1+A^2} + A^2$$

$$C^2 = 2\sqrt{1+A^2} - 1 - A^2$$

The equation is now in the form $K_2 = f(\beta, K_1)$, which is the desired answer.

COVER FACTOR TABLE

TABLE I. COVER FACTOR IN TERMS OF YARN NUMBER AND TEXTURE

This table provides solutions for the cover factor equation (3a)

For each yarn number listed above, textures are given over a range from 200 down to 11 yarns per inch.

Note: The yarn numbers in this table are singles equivalent

See sections in the body of the report for:

Organization of Table I (3a)

Solution of typical problems (5a)

Assumptions and limitations of tables (6)

BETA FACTOR TABLE

TABLE II. BETA FACTOR IN TERMS OF FILLING YARN NUMBER AND WARP YARN NUMBER

This table provides solutions for the beta factor equation (3b)

For each filling yarn number listed above, warp yarn numbers are given over a range of 100 down to 1.

Note: The yarn numbers in this table are singles equivalent.

See sections in the body of the report for:

Organization of Table II (3b)

Solution of typical problems (5b)

Assumptions and limitations of tables (6)

MAXIMUM WEAVABILITY TABLE

TABLE III. MAXIMUM FILLING COVER FACTOR IN TERMS OF WARP COVER FACTOR AND BETA FACTOR

This table provides solutions for the maximum weavability equations (3c)

In this table warp cover factors range from 10 (or 13, 15, 17) to 32, depending upon the weave.

Maximum filling cover factors range from 0.5 to 2.0

See sections in the body of the report for:

Organization of Table III (3c)

Types of problems (4a)

Solution of specific problems (5c)

Assumptions and limitations of tables (6)
